This pathway is common to both aerobic and anaerobic organisms, serving as the starting point for aerobic respiration.

Pyruvate Oxidation and Formation of Acetyl-CoA

Pyruvate produced in glycolysis is transported into the mitochondria (or equivalent in prokaryotes), where:

- Pyruvate is decarboxylated by the pyruvate dehydrogenase complex.
- This produces acetyl-CoA, NADH, and CO₂.

Acetyl-CoA then enters the Krebs cycle for further oxidation.

The Citric Acid Cycle: Complete Oxidation of Acetyl-CoA

Located in the mitochondrial matrix, the Krebs cycle involves a series of enzymatic reactions that:

- Oxidize acetyl-CoA to CO₂.
- Generate high-energy electron carriers NADH and FADH₂.
- Produce GTP/ATP directly through substrate-level phosphorylation.

Key enzymes include citrate synthase, isocitrate dehydrogenase, and α -ketoglutarate dehydrogenase.

Electron Transport Chain and Proton Gradient Formation

The electron transport chain (ETC) resides in the inner mitochondrial membrane (or plasma membrane in prokaryotes):

- Electrons from NADH and FADH₂ are transferred through a series of complexes (Complex I-IV).
- As electrons move, protons are pumped across the membrane, creating an electrochemical gradient.
- Oxygen acts as the final electron acceptor, combining with electrons and protons to form water.

This process is essential for establishing the proton motive force used in ATP synthesis.

Oxidative Phosphorylation and ATP Synthesis

Using the proton gradient, ATP synthase synthesizes ATP:

- Protons flow back into the mitochondrial matrix through ATP synthase.
- This flow drives the conversion of ADP and inorganic phosphate into ATP.
- Approximately 36-38 ATP molecules are produced per glucose molecule, depending on the organism.
